

EP-4

Require func → include a module to other

'require('./xyz.js)'

Module's protect their variables & func. from leaking.

Output: > in app.js.
in sum.js.

"func() is not defined." ERROR.

By default, func & vars are protected.

we have to explicitly import & export module.

Why this protection over modules is needed??

↳ if same var names are created, so there could be conflicts b/w files

There are 2 type of Module patterns.

Common JS Modules. (CJS)	ES Modules. (mjs)
→ <code>module.exports</code> <code>require()</code> ;	→ <code>export</code> <code>import</code>
→ by default used by node.js	→ by default in react & etc.
→ Older way	→ Newer way.
→ Synchronous way	→ Asynchronous way.
→ non strict mode	→ Strict mode ↳ can't declare variable without defining there datatype

NOTE,

→ `module.export` is an empty Object.

```
[  
  module.export.x = x;  
  module.export.calculateSum = calculateSum;  
]
```
